

LEACH: An Application-Specific Protocol Architecture for Wireless Microsensor Networks

**Wendi Heinzelman
Anantha Chandrakasan Hari Balakrishnan**

Massachusetts Institute of Technology

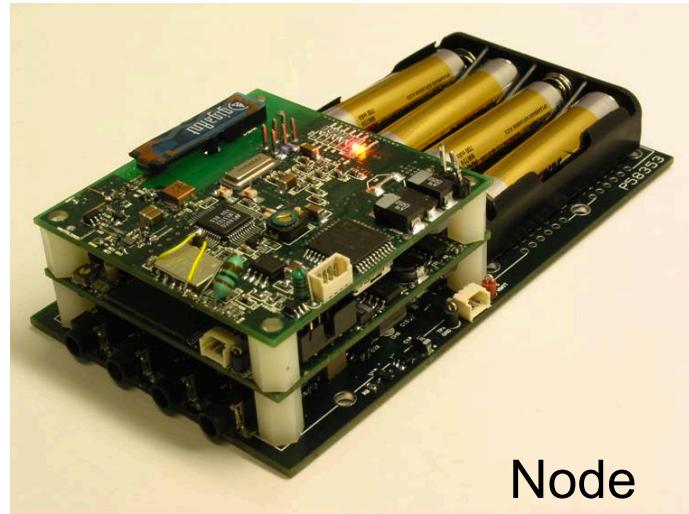

Sensor Networks

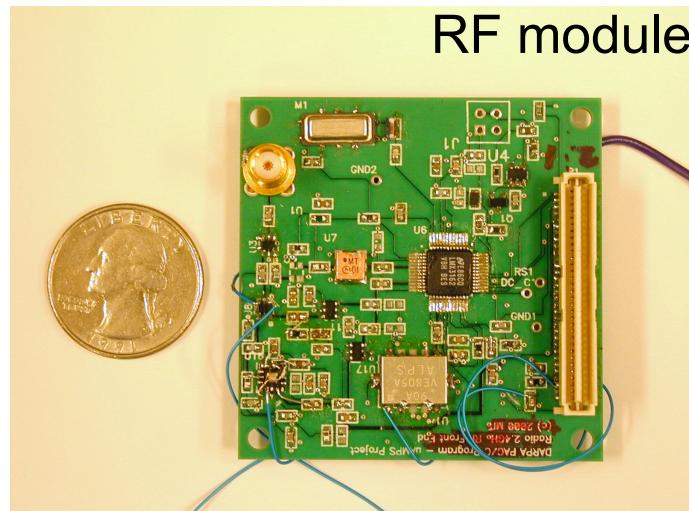

- **Remote monitoring of the environment**
 - Surveillance
 - Machine diagnostics
- **Relevant parameters:**
 - **System lifetime (energy efficiency)**
 - **Quality**
 - **Latency**

Context: MIT μ-AMPS Project (1999)

- **Energy-optimized sensors**
 - Node architecture and radio hardware
 - OS, algorithms, and protocols
 - **Assumptions:**
 - Base station far from nodes
 - All nodes energy-constrained
 - Locally, data correlated
 - **Communication protocols important**

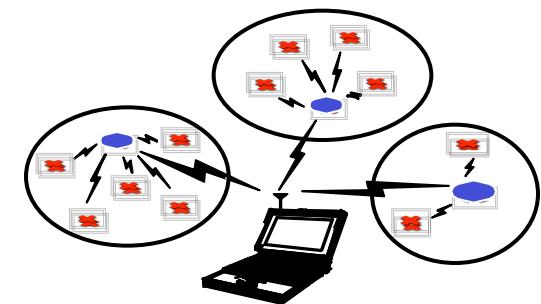

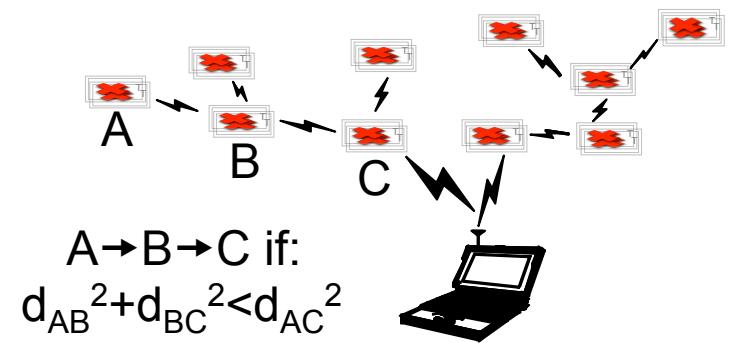

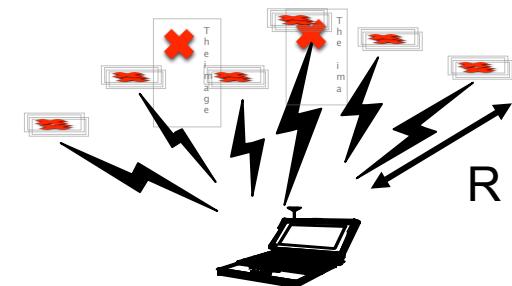

Node

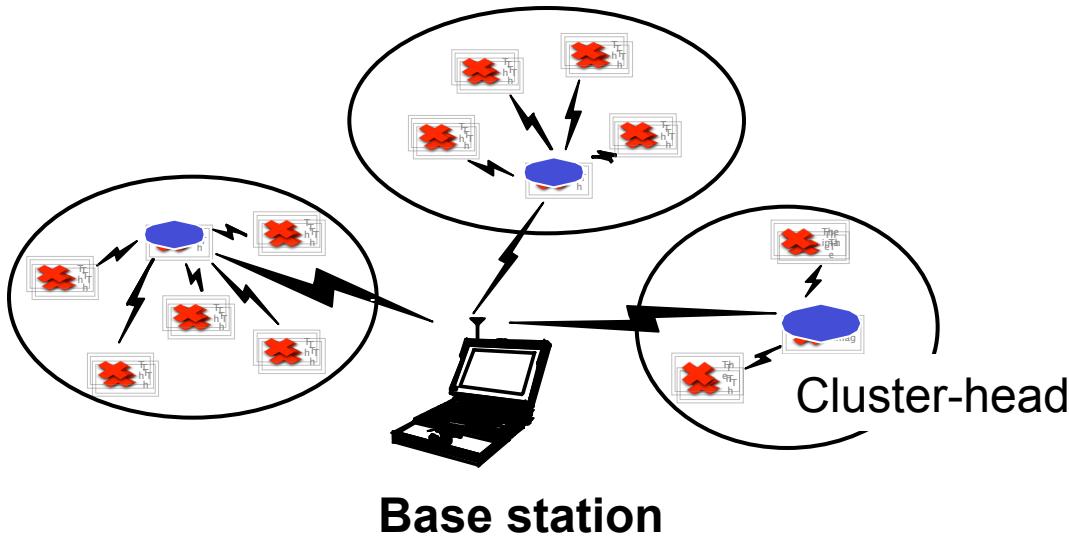

RF module

Prior Work

- **Direct transmission**
 - Energy scales as R^n
- **Routing**
 - E.g., Min transmission Energy
 - Multi-step communication
 - Short lifetimes for close nodes
- **Clustering**
 - Cellular model
 - Needs high-energy cluster-head

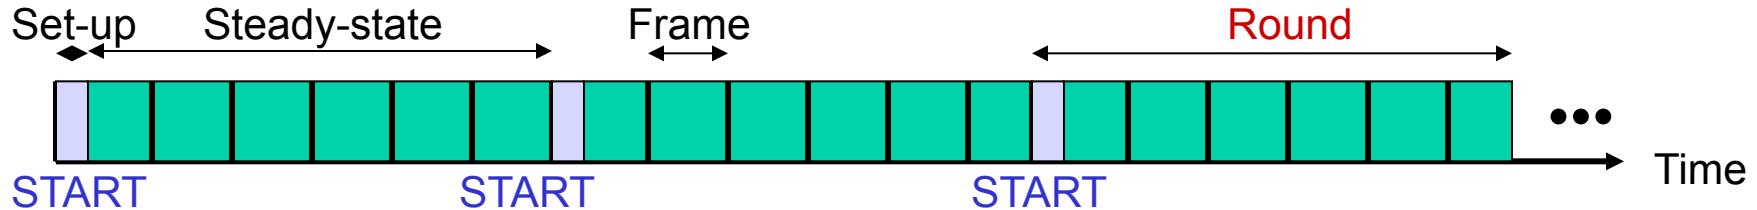

LEACH

- **Low-Energy Adaptive Clustering Hierarchy**
 - Adaptive, self-configuring cluster formation
 - Localized control for data transfers
 - Low-energy medium access
 - Application-specific data aggregation

LEACH Operation

- **Randomized cluster formation**
 - Each node decides to become cluster-head with some probability
 - Picked so the expected number of cluster-heads is k
 - k is a system parameter (and there's a way to pick a good k)
- **Rotate cluster-heads each round**
 - Clusters formed during set-up
 - Data transfers during steady-state
 - Requires nodes to be synchronized

Distributed Cluster Formation

$$E[\# \text{CH}] = \sum_{i=1}^N P_i(t) * 1 = k$$

$$P_i(t) = \begin{cases} \frac{k}{N - k * r \bmod(N/k)} & C_i(t) = 0 \\ 0 & C_i(t) = 1 \end{cases}$$

$r+1$ = current round of operation

k = system parameter

$C_i(t)$ = 1 if node i a CH in last r rounds

- Assumes nodes begin with equal energy
- Each node CH once in N/k rounds

Autonomous decisions lead to desirable emergent behavior

Unequal Initial Energies

$$P_i(t) = \frac{E_i(t)}{E_{total}(t)} k$$

$E_i(t)$ = energy of node i at time t

$E_{total}(t)$ = total energy in system at time t

High-energy nodes CH more often than low-energy nodes

If nodes begin with E_o

Cluster-head nodes

$$E_i(t) \approx E_o - X$$

Non-cluster-head nodes

$$E_i(t) \approx E_o$$

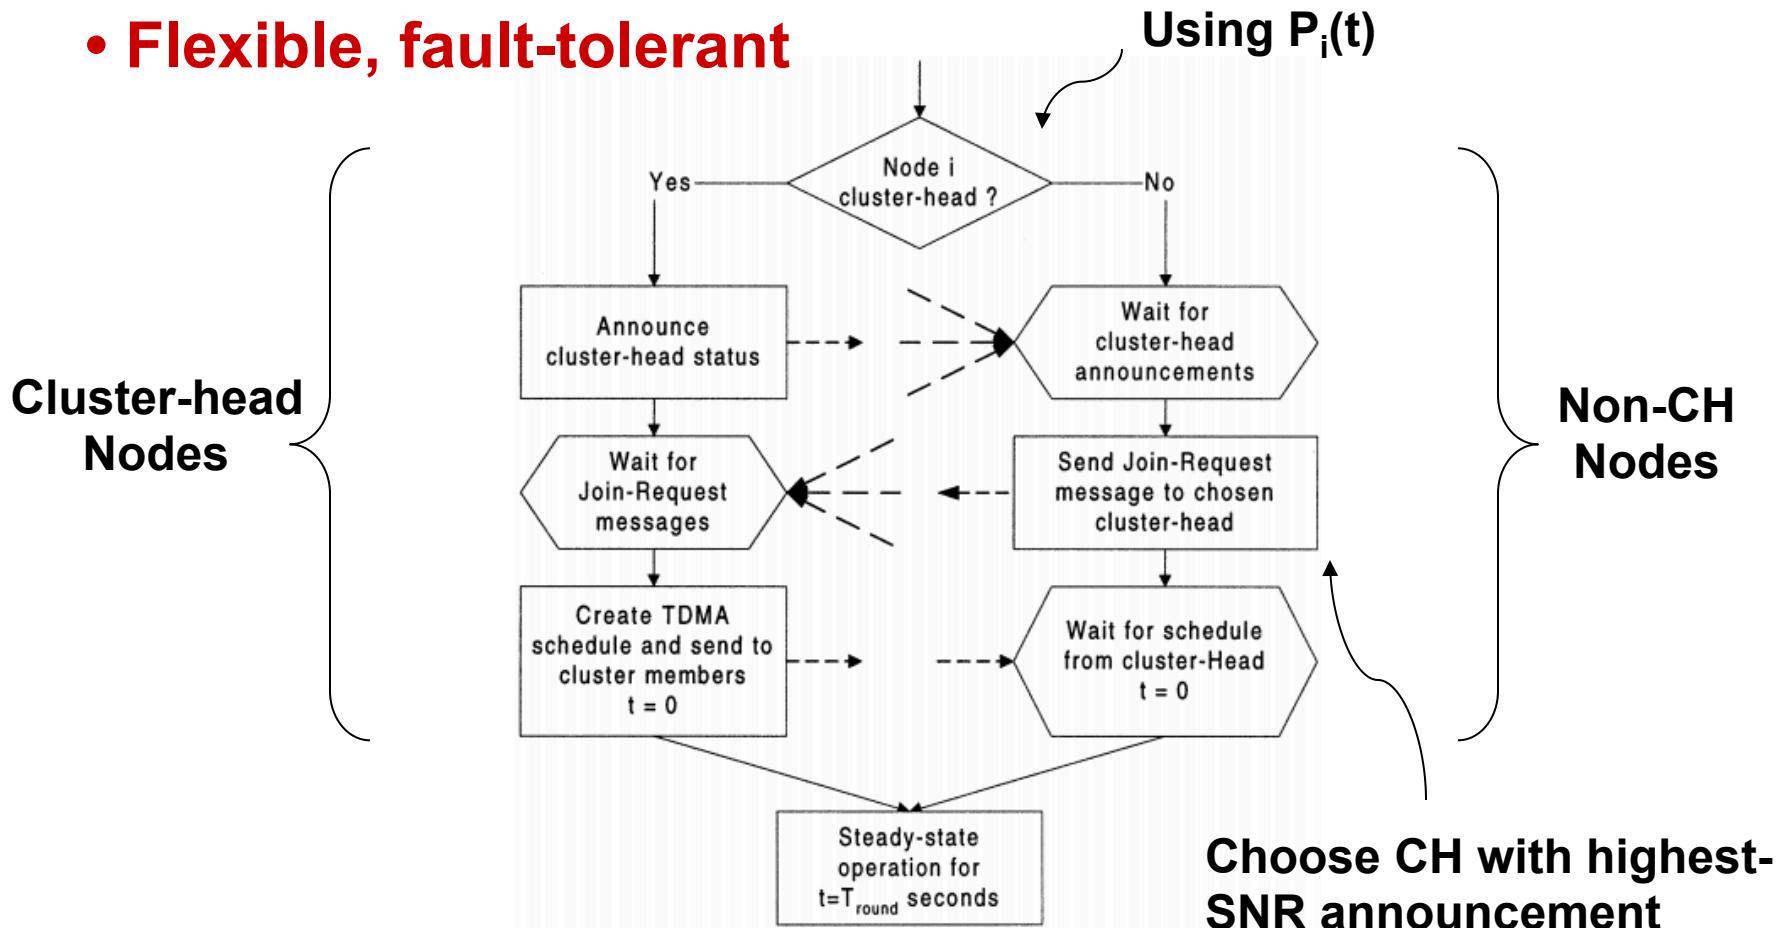

$$E_{total} \approx E_o(N-kr) + (E_o-X)kr$$

$$P_i(t) \approx 0$$

$$P_i(t) \approx k/(N-kr)$$

Distributed Cluster Formation Algorithm

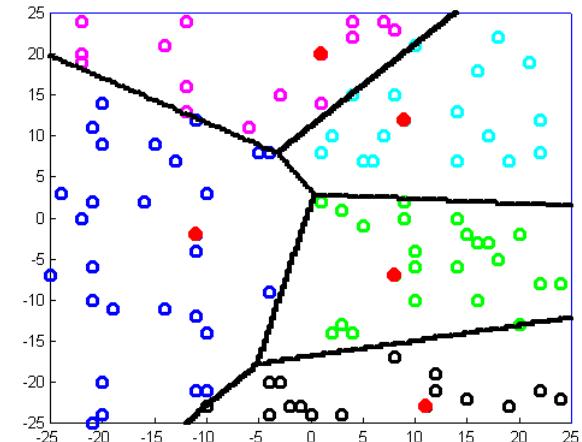

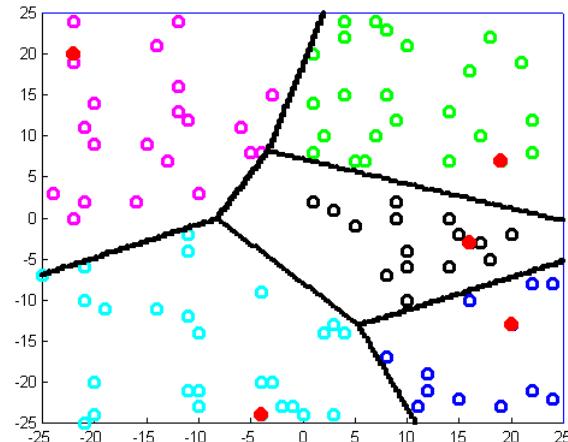

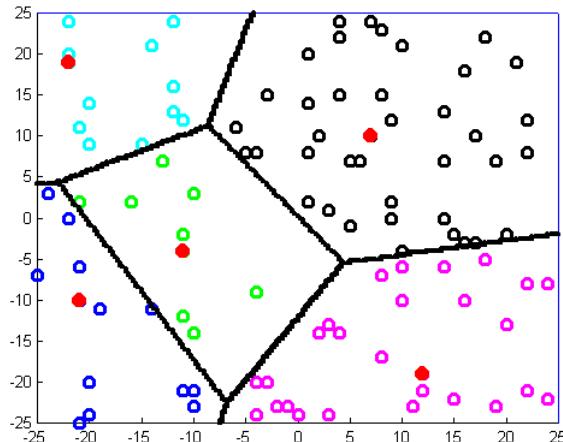

- No global control
- Flexible, fault-tolerant

Dynamic Clusters

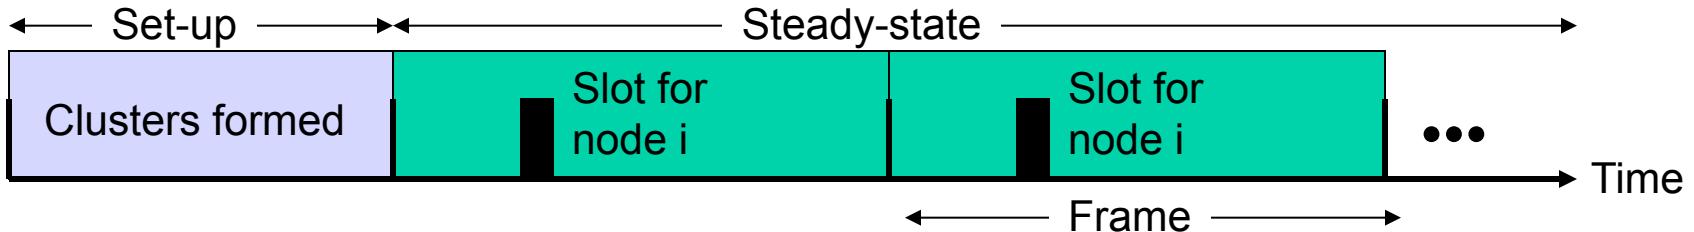

- Adaptive clusters
- Rotation to evenly distribute energy load

Clusters during different rounds in LEACH

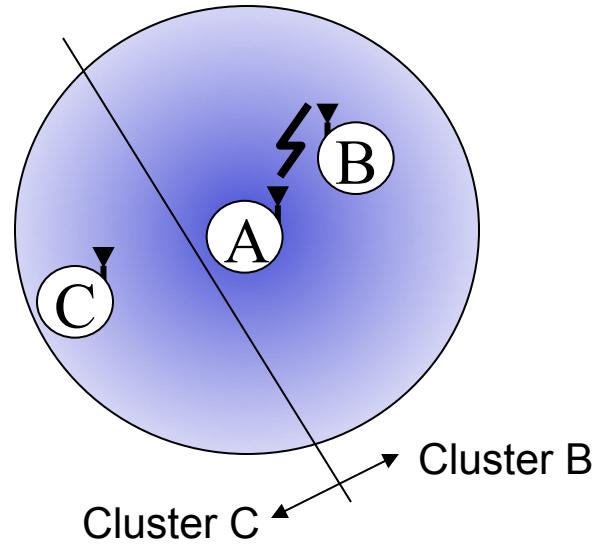

Cluster-heads = •

LEACH Steady-State

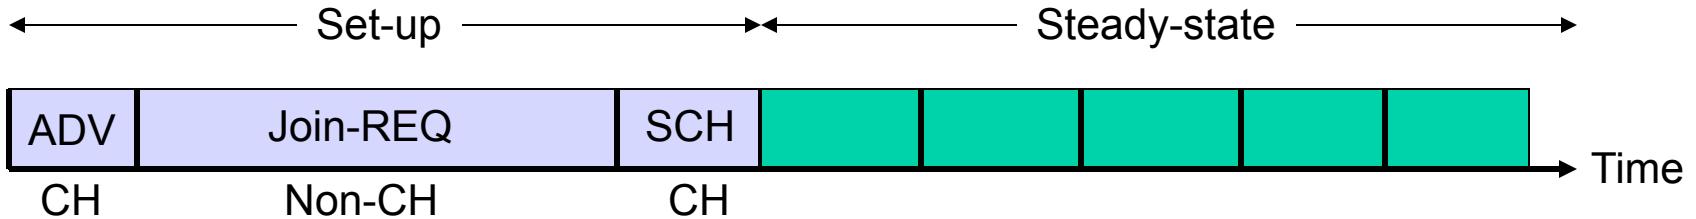

- **Cluster-head coordinates transmissions**
 - TDMA schedule
 - Node i transmits once per frame
- **Low-energy approach**
 - No collisions
 - Maximize sleep time

Inter-Cluster Interference

- **Transmission in different clusters can collide**
 - Nodes minimize transmission power
 - Each cluster has unique, orthogonal spreading code (e.g., CDMA codes)
 - Distributed solution to minimize interference

LEACH Medium Access

ADV

- CSMA
- Large power, small messages

Join-REQ

- CSMA
- Large power, small messages

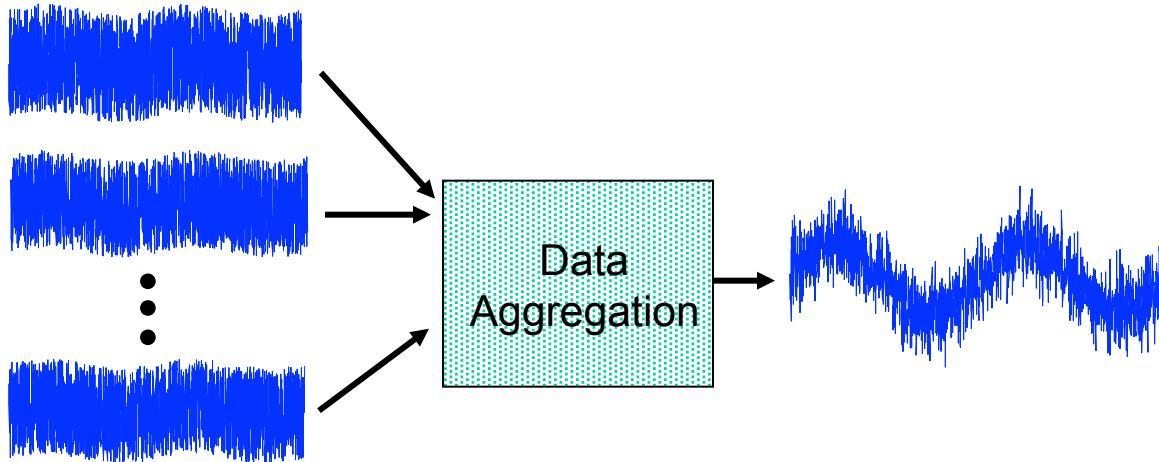

SCH

- CDMA code
- Power to reach all members

Data Transfer to CH

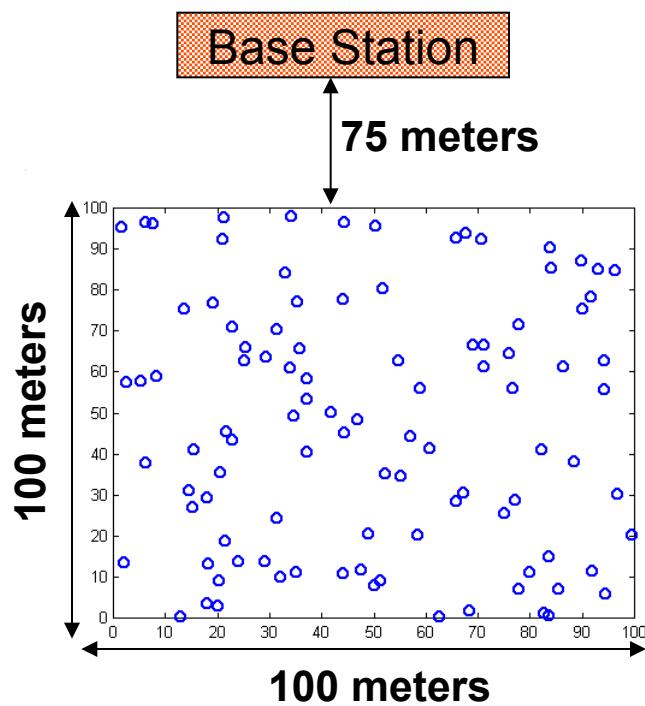

- TDMA (with CDMA code) – no collisions
- Power to reach CH, large messages

Application-Specific Data Aggregation

- Local sensor data often correlated
- Data aggregation
 - Common signal enhanced/noise reduced
 - Improved detection and classification
- Compute to reduce communication energy at cluster-head

Simulation Parameters

Nodes	100
Network size	100 m x 100 m
Base station location	(50,175)
Radio prop. speed	3×10^8 m/s
Processing delay	50 μ s
Radio speed	100 kbps
Radio electronics	50 nJ/bit
Transmit amplifier	100 pJ/bit/m ²
Beamforming cost	5 nJ/bit/signal
Data size	500 bytes

Optimum Number of Clusters, k

Analytic
Result:

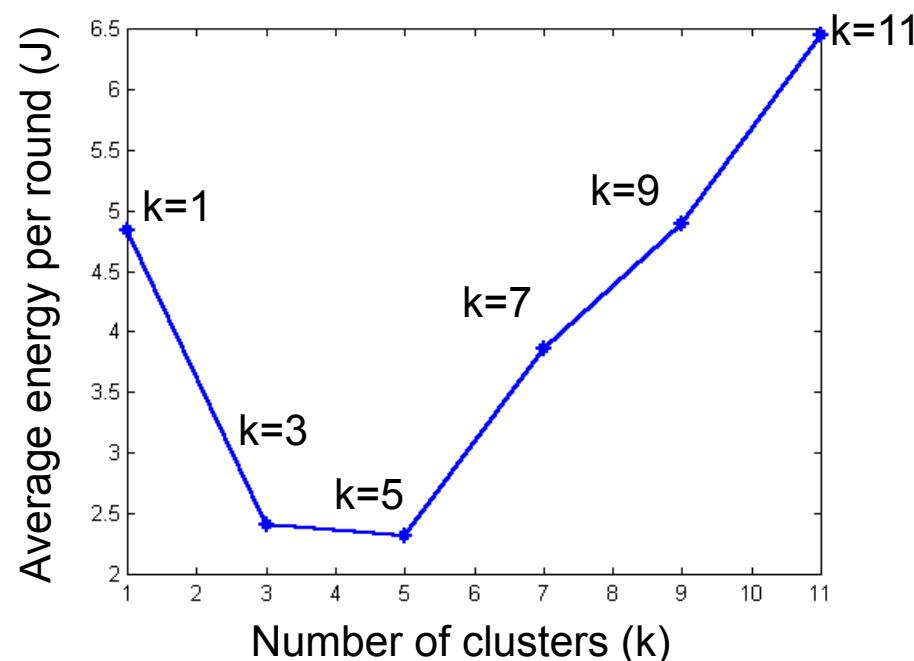

$$N=100$$

$$M=100$$

$$75 < d_{\text{toBS}} < 185$$

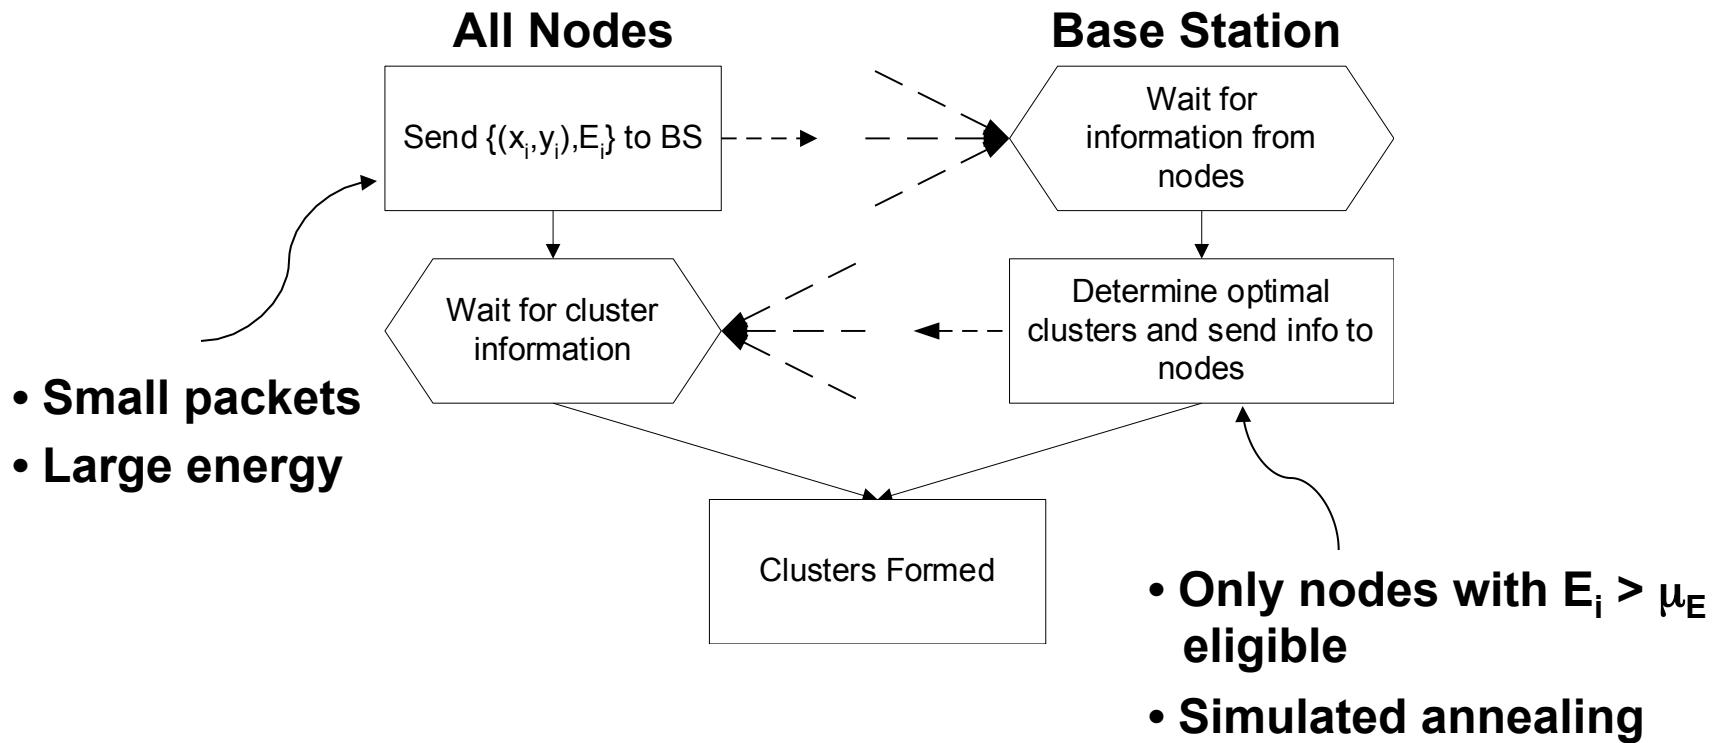

$\} \Rightarrow 2 < k < 6$

Simulation
Result:

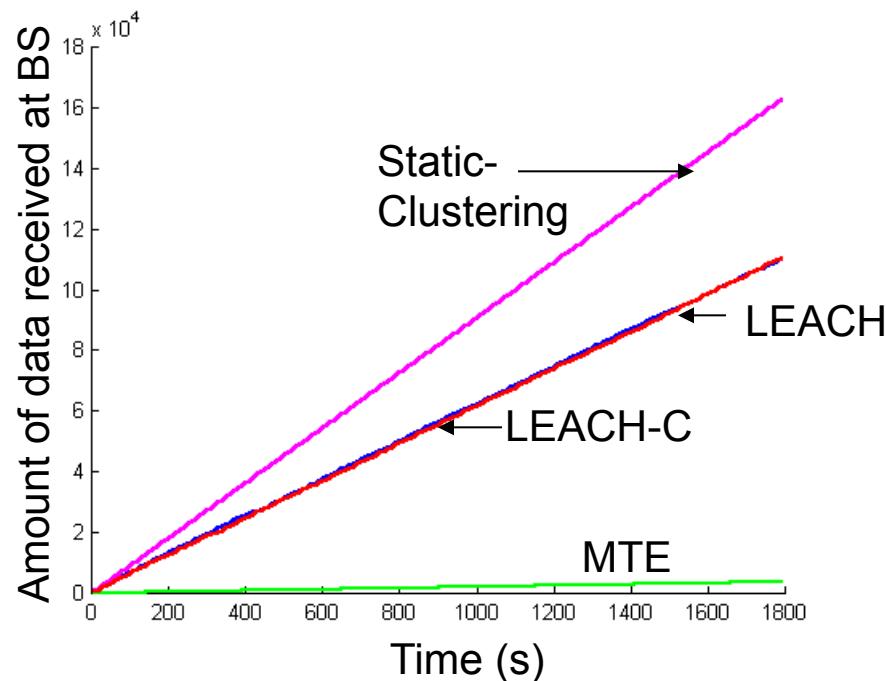

Centralized Cluster Formation (LEACH-C)

- Attempts to compute optimal clusters for comparison
- Needs GPS or other location-tracking method

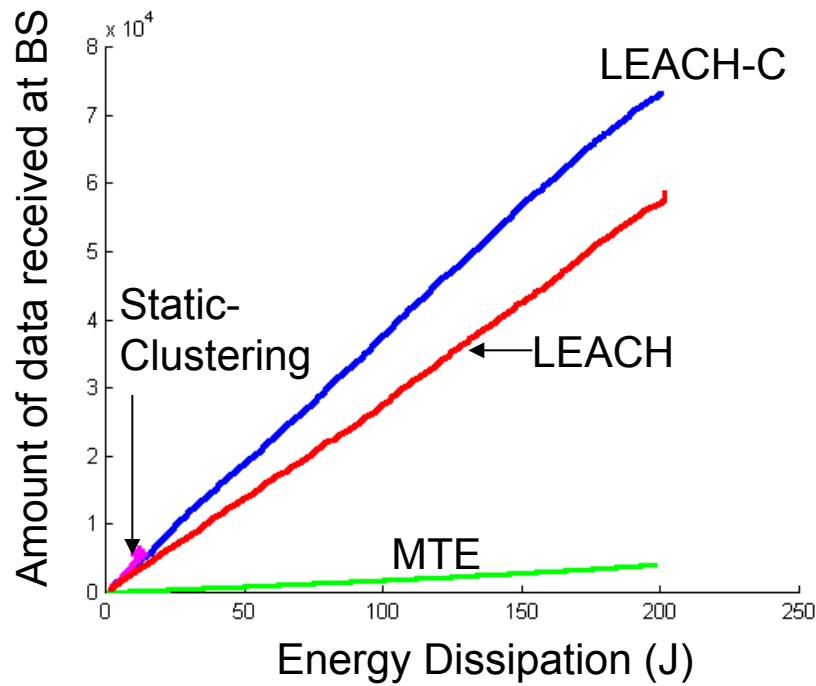

Simulations: Data Over Time (Assuming no energy constraints)

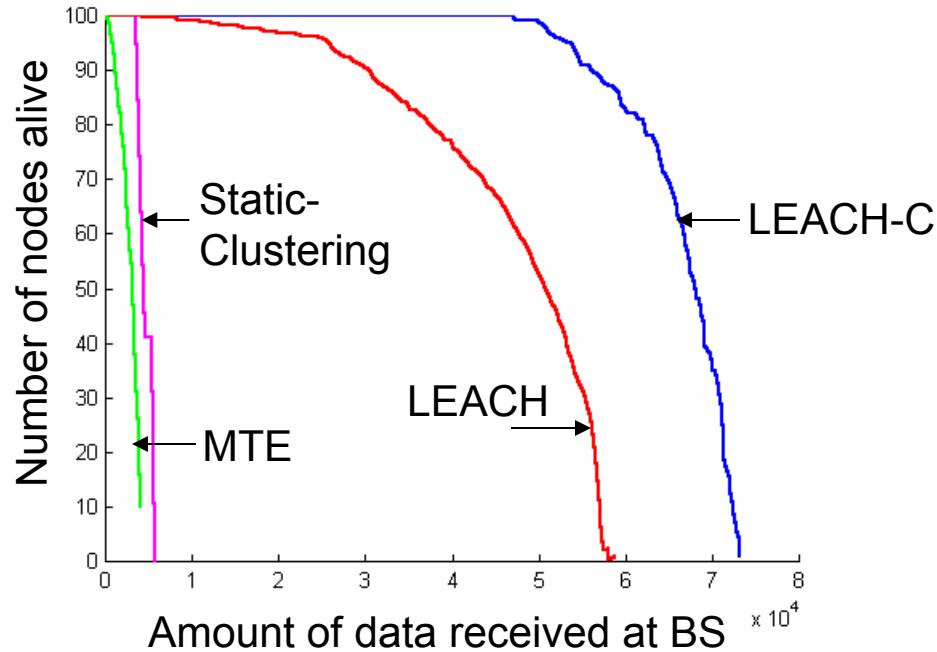

- **Static clustering: no set-up time**
- **LEACH data – 2 hops**
- **MTE data – 10 hops on average**

Simulations: Data per Energy

- LEACH achieves order of magnitude more messages per Joule
- Data aggregation successful

Network Lifetime with Limited Energy

- LEACH delivers over 10 times amount of data over system lifetime
- Rotating cluster-heads is effective
